Docket No. 3553-4075US3

APPARATUS, SYSTEM, AND METHOD FOR MAINTAINING A PERSISTENT DATA
STATE ON A COMMUNICATIONS NETWORK

5 **CROSS-REFERENCE TO RELATED APPLICATIONS**

The present application claims priority to U.S. provisional applications no. 60/177,462, filed January 20, 2000; US provisional application no. 60/178,986, filed January 28, 2000; and US provisional application no. 60/180,074, filed February 3, 2000, each of which are hereby incorporated by reference.

10 **FIELD**

The present application generally relates to computer systems and software, and more particularly to a method and system for a persistent data state on a communications network.

BACKGROUND

15 INFORMATION TECHNOLOGY SYSTEMS

Typically, users (i.e. people or other systems) engage computers to facilitate information processing. A computer operating system enables users to access and operate computer information technology. Information technology systems provide interfaces that allow users to access and operate systems.

20 USER INTERFACE

Computer user interfaces are analogous in many respects to automobile operator interfaces. Automobile operator interfaces such as steering wheels, gearshifts, and

09/207211-140300

5 Macintosh Operating System or Microsoft's Windows provide a system for accessing and displaying information. Such consumer-oriented operating systems enable users to access and operate computer information technology by providing an integrated user interface.

10 shell) and graphical user interfaces (e.g. X windows).

WORLD WIDE WEB

information technology systems (i.e. people using computers) are currently in use. An information navigation interface called WorldWideWeb.app, i.e. the web was developed in late 1990 on NeXT Computer Inc.'s operating system, NeXTSTEP, at the European Organization for Nuclear Research (CERN, a particle physics center). Subsequently, information navigation interfaces, i.e. web browsers, have become widely available on almost every computer operating system platform.

TRANSACTIONS

The onset of the web affected a tremendous increase in transactions occurring through insecure communications networks such as the Internet. Increasingly, such transactions occur via web page forms. In many instances, it is critical that data acquired over a communications network be acquired in a consistent, predictable, and reliable way. Otherwise, a host of problems may result such as failed transactions, application errors, incorrect orders, irritated customers, and other such consequences.

Many of the transactions occurring on the Internet have become more complex requiring a user to make multiple related interactions to complete a transaction.

These multiple related interactions are commonly referred to as a session. In other words, sessions refer to multiple user interaction states. Microsoft's Information Server may maintain a persistent state, i.e. a session. A persistent session makes an interaction state available for reference for a specified period of time.

SUMMARY

As set forth below, a need exists for an improved apparatus, system, and method for the tracking of a data state. Particularly, a need exists to create persistent session data across several information servers. Various attempts to solve this problem have been made. Such attempts include Microsoft's Information Server, which employs a built-in session object. Although this session object works for web sites running on a single server and with low reliability requirements, it is inoperable beyond that limited scale. The present

BRIEF DESCRIPTION OF THE DRAWINGS

The accompanying drawings illustrate certain embodiments of the invention.

Figure 1 illustrates a centralized controller according to one embodiment of the present invention;

Figure 2 illustrates another embodiment of the present invention in the form of a distributed system interacting through a communications network;

Figure 3 illustrates another embodiment of the system and various interactions;

Figure 4 illustrates web pages, hypertext, reference and proximal links;

10 Figure 5 illustrates a persistent session in progress;

Figure 6 is a flowchart illustrating a persistent session creation system;

Figure 7 is a flowchart illustrating a persistent session navigation system.

DETAILED DESCRIPTION**CENTRALIZED CONTROLLER**

Figure 1 shows one embodiment of a system incorporating the present invention. In this embodiment, the system includes a centralized controller 1101 configured to receive information from one or more users from user input device(s) 1114. The centralized controller may also receive information from a communications network 1115 through its input/output (I/O) facility 1105, preferably, via a network interface 1107. The I/O facility is capable of both receiving and sending information. Peripheral devices 1116 may be attached to the centralized controller for any number of purposes including, but not limited to: printers for output, scanners for input, additional or alternative storage devices for data storage and retrieval, network interfaces for communication, and other like devices.

A typical centralized controller may be based on common computer systems that may include, but are not limited to, components such as: a central processing unit (CPU) 1104, random access memory (RAM) 1103, read only memory 1102, and a local storage device 1108. The CPU is electronically coupled to each of the central controller's other elements. The CPU comprises at least one high-speed data processor adequate to execute program modules for executing user or system-generated requests. These modules are described in Figures 2 through 7. Preferably, the CPU is a conventional microprocessor such as an Intel Pentium Processor. The CPU interacts with RAM, ROM, and storage device(s) to execute stored program code according to conventional data processing techniques.

5

10

15

20

interface device 2202, a session server controller 2203, a web browser controller 2204, a database controller 2205, and an information server controller 2206.

A user interface controller is configured similarly to the centralized controller of Figure 1 except it does not require a database, session server, information server, or web browser. A user interface 2110 is stored program code that is executed by the CPU. The user interface is responsible for receiving either user or system-generated requests.

In alternative embodiments, a user interface device 2202 may take the place of or be used in conjunction with a user interface controller. The user interface device may be a telephone, a consumer electronics online access device (e.g. Phillips Inc.'s WebTV), PDA or the like.

In one embodiment, a centralized server 1101 is configured as a web server, and conventional communications software such as Netscape Navigator web browser may be used to transmit a conditional purchase offer (CPO). In one embodiment, the CPO centralized server 1101 has a web page on the web, allowing a buyer to provide information through the interface of the conventional web browser software. In one embodiment, the buyer selects the subject of the goods she wishes to purchase by selecting from a list of possible subjects. Subjects might include airline tickets, hotel rooms, rental cars, insurance, mortgages, clothing, etc. After the subject is selected, a form is displayed on a video display monitor of a buyer interface. This form is an electronic contract with a number of blanks to be filled out by the buyer, with each blank representing a condition of a CPO.

An information server controller is comprised similarly to the centralized controller of Figure 1 except it does not require a session server, database, web browser, or user interface. An information server 2106 is stored program code that is executed by the CPU. The information server may be a conventional Internet information server such as Microsoft's Internet Information Server revision 4.0. The information server may allow for the execution of program modules through facilities such as C++, Java, JavaScript, ActiveX, CGI scripts, ASP, or any like facility with regular expression (regex) abilities on the server side. An information server typically takes requests from a web browser and provides results to a web browser; however, an information server can take requests from user interfaces as well. The information server may also take system requests. In alternative embodiments, a information server may be integrated into a user interface or vice versa, thus, combining the functionality of both.

A session server controller is configured similarly to the centralized controller of Figure 1 except it does not require a database, web browser, information server, or user interface. The session server 2109 is stored program code that is executed by the CPU. A session server takes requests from a user interface and provides results to a user interface. The session server may also take system requests. In Figure 1 the session server is implemented within an information server, however, the session server may also be implemented independently and interact with an information server through provided APIs as illustrated in Figure 2 2106 and 2109.

A database controller is configured similarly to the centralized controller of Figure 1 except it does not require a session server, web browser, information server, or user interface. A database(s) 2113 is stored program code that is executed by the CPU and it is stored data processed by the CPU. A database takes requests from a session server and provides results to a session server. The database may also take system requests. In an alternative embodiment, a session server may be integrated into a database or vice versa, thus, combining the functionality of both. In yet another alternative embodiment, a session server may be integrated into a user interface or vice versa, thus, combining the functionality of both.

A web browser controller is configured similarly to the centralized controller of Figure 1 except it does not require a session server, database, information server, or user interface. A web browser 2112 is stored program code that is executed by the CPU. The web browser may be a conventional hypertext viewing application such as Microsoft Internet Explorer or Netscape Navigator. The web browser may allow for the execution of program modules through facilities such as Java, JavaScript (preferably revision 1.2 or greater), ActiveX or any like facility with regular expression (regex) abilities. A web browser takes requests from a user interface and provides results to a user interface. The web browser may also take system requests. In alternative embodiments, a web browser may be integrated into a user interface or vice versa, thus, combining the functionality of both.

The functionality of the user interface controller, session server controller, database controller, information server controller, and web browser controller may be

combined in any number of ways to facilitate deployment. To accomplish this, one may simply copy the executable code, first ensuring it has been compiled for the appropriate CPU of the controller for which it is destined, and/or data onto a local storage device of one of the various controllers. Similarly, the functionality of the user interface, session server,
 5 database, information server, and web browser may be combined in any number of ways to facilitate deployment. To accomplish this, one must simply integrate the components into one code base or in a facility that can dynamically load the components on demand in an integrated fashion.

SYSTEM AND VARIOUS INTERACTIONS

10 Figure 3 shows an overview of the basic interaction of the system. The information server 3106 acts as an in-between for: a user interface 3110 on a system, a user interface device 3202, or a web browser 3112 taking requests. The information server can make further requests of a session server 3109 that itself may access one or more databases to access stored session states or other information. Both the information server and the session
 15 server may service multiple instances of any of the aforementioned. Also, there may be one or more instances of the session server and/or information server that may severally or jointly interact with one or more information servers 3106. Session servers service information servers. In turn, the information servers and/or session servers may interact and service one or more databases 3113 for various purposes such as, but not limited to: validation rules,
 20 session state storage, and electronic commerce (E-commerce) order fulfillment. Figure 3 shows that the session server and information server may service multiple sources at once,

5 WEB PAGES

10 One may view hypertext at an initial reference navigation location 4404b by traversing an initial reference link. The subsequent reference links 4403b found in the hypertext found at the initial reference navigation location are also proximal links, however, they are one reference less proximal (i.e. one “hop” away) to the originating navigation location.

20 PERSISTENT SESSION

Figure 5 illustrates a persistent session in progress. This illustration is for purposes of example only, and in no way should be considered a limited application or implementation of the present invention. Initially, a web browser displays a web page that starts a persistent session and contains various web form fields 5501. This web page is

5 illustrated with an example order for jelly beans, however, any number of uses may be employed for maintaining a persistent session. The user enters items into web fields 5502. After having entered information into each of the web fields the user may advance to the next web form segment by engaging a button 5503a or other facility of the like designed to advance the web browser to another web form segment by employing standard data

10 processing techniques. Upon engaging the next web form segment button, the first session state will be saved and the web browser will advance to the next web form segment 5504. In this web page, the user may enter more information into web fields; in this example the user provides customer information. Upon completion of these fields, the user may engage a button triggering the advance to the next web form segment 5503b, thereby saving the

15 second session state, i.e., doing so will send the information entered into the web form to a session server via HTTP or other such transfer protocols and/or elsewhere as described in Figures 6 and 7. After submitting the order 5503b at the end of the web form segments, an information server might check for the validity of entries. In this example, the user entered

20 wrong information into the quantity field 5502a in the first session state. Having access to saved session states allows the web browser to restore the first session state 5501 so that the user can access the web page without losing their information provision 5505, identify the

PERSISTENT SESSION CREATION

5

10

15

20

The session server generates a user session key 6603. This key is a unique session identifier and associates only with the user and no others. In one embodiment, the association employs the user's IP address for security reasons. However, a multitude of other standard data processing implementations may be employed such as, but not limited to:

5 associating a session to a user supplied identifier and password, an encrypted user supplied key such as a PGP key, and other implementations of the like. One implementation generates a key based on the user's IP address, and a date and time stamp so that user session keys may be made to expire after a set time. This consequently creates a session that is unique across any number of distributed controllers.

10 Upon generating the user session key, the session server provides the session key 6604. The provision of the user session key may be implemented in any number of standard data processing embodiments such as, but not limited to: sending the user session key directly to the user; providing the user session key to the information server, which may in turn advance it to the user; providing the user session key to the information server, which
15 may in turn imbed the session key into a web page for the user. In one embodiment, the key is imbedded into a web page, thus, reducing the number of client-server transfers.

Upon provision of a user session key, an information server provides a web page 6605. In alternative embodiments, the provision of the requested web page may occur at any point after it is requested. Upon making the user session key and requested web page
20 available, the user obtains both 6606. The order in which the user obtains the page and/or

user session key is not important, however, one embodiment will provide the user with the user session key imbedded in the web page to increase transfer efficiency.

Upon obtaining the user session key, the session key is saved 6607, in one embodiment, on the client within a cookie. Alternatively, the user session key may also be saved on the server and provided to users upon the provision of uniquely identifying information such as, but not limited to: a unique identifier (e.g. a user name) and password, an IP address, a combination of both, and others of the like. However, it is preferable to employ the client for saving the user session key to reduce client-server transfers:

PERSISTENT SESSION NAVIGATION

Figure 7 outlines a persistent session navigation system (PSNS), and further describes a persistent session of Figures 5 and 6. In one embodiment, a persistent session navigation system is comprised of a traverse and recall subsystem 7701, a provide and save subsystem 7702, and optionally of a verification subsystem 7703. However, employing standard development techniques, the PSNS may be implemented by not only reordering the subsystems, but also by combining and intermeshing the subsystems.

Upon the creation of a persistent session as detailed in Figure 6, a user will navigate to an appropriate form segment 7704. Thereafter, the appropriate form segment is provided 7705 employing standard data processing techniques such as, but not limited to, obtaining the web page (segment) from: cache, in memory, an information server, or other facility of the like. Upon the user's navigation to the appropriate form segment, session information for the form segment is provided 7706, employing standard data processing

5 In one embodiment, session data (i.e. session information) includes text entries made into web form fields, (pop-up) menu selections, user interface selections (e.g., check boxes), and or the like. In one embodiment, the session data is saved as HTML, ASCII text, and or the like. In alternative embodiments, the session data may be encrypted, saved as binary, and or the like formats. Session data may be provided 7706 upon any triggering event to a session server and or local storage. In one embodiment, the session update occurs when selecting a button, e.g., 5503a of Figure 5. The button might generated by, contain, and/or be associated with HTML, Javascript, and/or the like, which takes the user entries in a web form, i.e., session data, and sends them to a session server and/or local storage. In another embodiment, a web page may have HTML, Javascript, and or the like embedded within, which periodically executes sending session data updates to a session server and/or local storage.

20

the like. The user may attempt to advance to the next form segment as outlined in Figure 5 by selecting a link or other like mechanisms.

Upon the user's attempt to advance to the next form segment, the session state is updated 7709. A session state is a session key with associated session data. In one

5 embodiment, both the session key and session data are stored together on a session server. In an alternative embodiment, session keys may be saved separate from associated session data, i.e., session keys may be stored on a session server with references to the locations of associated session data. In one embodiment, a session server will save every session state update, i.e., user entered web form data sent at every triggering update event; such an
10 embodiment allows for stepping back in time through the progression of a user data entry session. In an alternative embodiment, only a single session state is maintained and updated at the session server. In yet another embodiment, session data is saved in a cookie, file, and/or the like local storage facility and only a session key is saved at the session server; this embodiment reduces network transactions and server resource requirements. In one
15 embodiment, local cookie saving of session data may be achieved by generating a session key that references a local cookie, file name, and or the like.

In an alternative embodiment, the session state may be updated with finer granularity; i.e. the session state may be updated as the user provides information going from web form field to field. The session state information may be updated to any number of
20 facilities such as, but not limited to: memory, cache, file(s) (i.e. cookie(s)), session server(s), information server(s), or like facility. In one embodiment, the session state information is

5

10

15

server. The latest session information may be identified by time and date stamps provided by the operating system, database record creation time date stamps, and or the like.

It should be understood that the above description is only representative of illustrative embodiments. For the convenience of the reader, the above descriptions have focused on a representative sample of all possible embodiments, a sample that teaches the principles of the invention. The description has not attempted to exhaustively enumerate all possible variations. That alternate embodiments may not have been presented for a specific portion of the invention or that further undescribed alternate embodiments may be available for a portion is not to be considered a disclaimer of those alternate embodiments. It will be appreciated that many of those undescribed embodiments incorporate the same principles of the invention and others are equivalent. Thus, it is to be understood that the embodiments and variations shown and described herein are merely illustrative of the principles of this invention and that various modifications may be implemented without departing from the scope and spirit of the invention.
